Student No. 1155264976

One recent AI-related development that changed my perspective is Meta's Muse personal AI agent. Muse shows a future in which AI is no longer just a chatbot that answers questions, but a personal assistant that can browse the web, connect with different applications, and complete tasks on behalf of users. Meta has also recently expanded Muse with more connectors and integration with AI glasses, which makes this vision seem increasingly realistic.

However, this development also made me more aware of the practical barriers to personal AI. Even if an AI agent is technically capable of completing a task, many websites may block automated access, while some applications do not provide sufficient permissions or APIs for AI agents to interact with them. Privacy and security concerns also mean that companies may be reluctant to give AI systems full access to user accounts and sensitive information. Therefore, I now believe that the main challenge for personal AI is not only improving the intelligence of the model, but also building a broader ecosystem in which websites, applications, and AI agents can securely interact with one another.

This has slightly changed my career perspective. Previously, I paid more attention to the capabilities of AI models themselves. Now I think the infrastructure, APIs, security mechanisms, and business partnerships behind AI agents may be equally important. In the future, I would like to develop a better understanding of how AI products can be integrated into real business processes, rather than focusing only on what AI models are theoretically capable of doing.
